                        Abstract:
                                   this module contains all the routines necessary to perform directory wildcarding in file specification processing.
                        Environment:
                                   vax/vms
                        Author:

Thompson 26-Jan-1983 fix a bug when parsing []*.*;* when in the last sub- directory by putting in a check the first time through in nextdir to see if we are all the way down. KBT0218 Keith B. Thompson 23-Aug-1982 Reorganize psects KEK0018 K. E. Kinnear 9-Feb-1982 Fix ASSUME for SWB offset into translation buffers for new length of FWA\$T_NAMEBUF. JWH0001 Jeffrey W. Horn 18-Jan-1982 fix broken subroutine branch. TMK0025 Todd M. Katz 16-Dec-1981 Rip out all SDI stuff in RM\$NEXTDIR. RMOWILD will not (better not) be called for anything but files on disks. Also FWA\$B_DIRWCFLGS is being set incorrectly on repeated searches involving ellipsis traversal because it is not being set to the value it had after parse before the match routine is called. Fix this bug by resetting FWA\$B_DIRWCFLGS to the value it had (before the first search began) before the match attempt is made. This will mean no change in it if there were no ellipsis, but if there were it will end up being set to the new value on a successful match. TMK0019 Todd M. Katz 25-Nov-1981 Skip any subtrees rooted at null length directory filenames. Such subtrees are pruned, and their contents NOT searched. TMK0018 Todd M. Katz 18-Nov-1981 Initialize certain control fields within the SWB to their correct values for UIC directories even if these fields are not needed for wildcard processing. This is to avoid confusion when these fields are looked at. TMK0014 Todd M. Katz 12-Nov-1981 Change a BBC to a BBC so that the flag SWBSV FIRST is always cleared after the first time through RM\$NEXIDIR

Todd M. Katz

28_Aug_1981

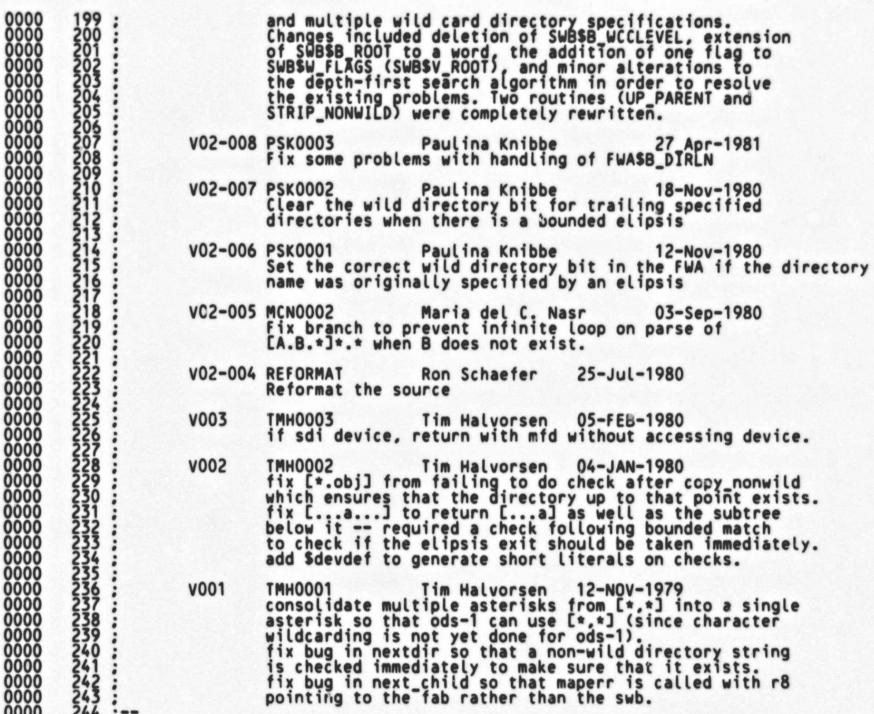

Performance enhancements. Initially, all leading nonwild tokens are made part of the directory string, and their existance is confirmed. Then, each and every remaining token in the pattern string up to, but not including the first ellipsis, represents the pattern for the directory name that is to match it, and these are resolved. All branches below the level of the root of the first ellipsis must be searched for any and all directories. If there are no ellipsis, or above the root of the first ellipsis, crosswise directory tree traversal can only occur if wild nonellipsis tokens were encountered. After each directory name is resolved, a call is made to a matching routine to determine whether the directory string now matches the entered pattern. This routine returns partial or total success, and it can only return failure when it is impossible to match the trailing tokens while within a bounded ellipsis traversal. NOTE: the number of characters in a directory specification is limited to 81 although theoretically it would be possible to have (8 levels * 9 + 8 ... * 3 + 2) = 98 characters.

V02-013 TMK0006 TMK0006 Todd M. Katz 21_Aug_1981 Complete rewrite. The algorithm upon which this module had Complete rewrite. The algorithm upon which this module had been formerly based was scrapped, and a completely new one substituted. The new algorithm guarentees that each and every directory specification matching an inputed pattern is touched only once by performing a "pruned" pre-order traversal, and returning only those directories matching the inputed pattern string. Pruned in the sense that not all directories are touched, but rather, as few as possible. Various optimizations have been implemented to reduce extraneous calls to the ACP, and several more, which are required, will be included within a succeeding enhancement.

Checked this in as new module. Previous edit history invalid.

- V02-012 KEK0007 K. E. Kinnear 11-Aug-1981 Change IFB\$L_AS_DEV to IFB\$L_PRIM_DEV where necessary.
- V02-011 TMK0005 TMK0005 Todd M. Katz 11_Aug_1981
 Delete errant ASSUME statement within FIND_DIR. It was no longer needed with the addition of the new field FWAST_WILD.
- TMK0004 Todd M. Katz 10 Aug_1981 Correction of the parameter FWA\$C_MAXDIRLEN to its correct size of 81 resulted in a much larger SWB. Since only 79 bytes are required ([] are not copied into SWB\$T_PATTERN), a change was made to reflect this and to take advantage of a new scratch field, FWA\$T_WILD. V02-010 TMK0004
- TMK0001 Todd M. Katz 29_Jul_1981 Fix some problems with handling of bounded elipsis V02-009 TMK0001

```
.SBTTL RM$INIT_SWB, Initialize SWB for Wildcarding
                            :++
                               RM$INIT_SWB: initialize swb for wildcarding
                                       this routine takes the parsed directory specification, and recreates the input file directory specification, minus the delimiter brackets, in the SWB for later use. It also initializes various fields within the SWB for use later on.
                               Inputs:
                                        r9 = ifab address
                                       r10 = fwa address
                               Outputs:
                                        RO success/fail

we divide ACP errors into two catagories - fatal and nonfatal. nonfatal errors, such as no more subdirectories within the current directory specification, are handled by this module. fatal errors maybe handled by this module depending upon their nature. both types of errors usaully result in the traversal continuing, but in a crosswise manner one level up from the level of the current directory specification.

.SBTTL MATCH, Compare Directory Specification with Pattern String
                                                  MATCH:
                                                                            compare directory specification with pattern string
                                                             this routine is responsible for comparing the current directory specification with the current pattern string, it makes this comparison one token/pattern at a time, recursively calling itself with the
                                                              remainder of the pattern string and/or directory specification when it finds the current token matches the current directory name. the algorithm employed will try all possible matching combinations when ellipses are involved inorder to attempt to find a suitable
                                                             configuration. note that it is in the very nature of the directory wildcarding algorithm, that this routine can fail only when we have traversed down too deeply, because of an ellipsis, such that the input pattern can never be matched. most often, a status of total or partial success is returned, and in the latter case, information about the next directory to look for is returned as well.
                                                   inputs:
                                                                   = descriptor index of current directory name
                                                              r8 = swb
                                                              r10 = fwa
                                                   outputs:
                                                              r0 = true if match was successful, false for fatal
                                                              r1 = degree of success - total or partial
                                                                       meaningless if r0 = false
                                                              FWASB_DIRWCFLGS is set appropriately if the match was totally
                                                              successful, trashed otherwise
                                                              SWB$L_SCRATCH_PAT contains information about the next directory to search fo
                                                              when a status of partial success is returned
                                         864 MATCH: MOVQ
                                                                            FWA$Q_DIR1(R10)[R6],R2 ; get current directory's descriptor
0130 CA46
                     7D
                                                    if there are tokens remaining but no directories, this means that not
                                                   enough of the tree has been downward traversed to match the input pattern string, a status of partial success is returned so that the downward traversal will continue as is required, there is one exception, if the current token is an unbounded ellipsis (and thus the last token), it
                                                    matches the empty current directory, so a status of total success is
                                                    returned.
                                                                            SWB$B_PATLEN(R8)
70$
R2
                                                                                                                          if there are no more tokens left
                                                               TSTB
                                                              BEOL
                                                                                                                          then branch to handle that condition if both tokens & directories are left

The working set limit was 1950 pages.
127870 bytes (250 pages) of virtual memory were used to buffer the intermediate code.
There were 120 pages of symbol table space allocated to hold 2295 non-local and 96 local symbols.
1430 source lines were read in Pass 1, producing 16 object records in Pass 2.
27 pages of virtual memory were used to define 26 macros.
